Risk analysis and vulnerability remediation

The risk analysis ISO 27001/2, 31000 - the most important, but an optional step!

A vulnerability is only a problem if it can be exploited by hackers. It makes it possible to violate the security objectives in data protection if, for example, security measures are missing or a threat is not fully covered.

Vulnerabilities can also occur in security measures themselves, for example through faulty software updates. They represent a deficit in the principles of data protection implementation.

We carry out an independent risk analysis, because this is the only way to uncover potential dangers: it includes the identification and correlation of risks, the analysis of their causes, their probability of occurrence, their frequency, the evaluation of risks and suitable measures for risk reduction. In this way, risks become controllable and manageable.
